(54) Radiation image detector

(57) A radiation image detector wherein a photo-stimulable phosphor screen (23), a source of stimulating light (24) and an array of transducer elements (25) are enclosed within an enclosure that is hermetically

closed against humidity. In one embodiment the enclosure is flushed with an inert gas such as N₂ gas.

Fig. 1

Description

FIELD OF THE INVENTION

[0001] The present invention relates to digital radiography and relates more specifically to a system wherein a radiation image is temporarily stored in a photostimulable phosphor screen.

BACKGROUND OF THE INVENTION

[0002] Radiation image recording systems wherein a radiation image is recorded on a photostimulable phosphor screen by exposing said screen to image-wise modulated penetrating radiation are widely used nowadays.

[0003] The recorded image is reproduced by stimulating the exposed photostimulable phosphor screen by means of stimulating radiation and by detecting the light that is emitted by the phosphor screen upon stimulation and converting the detected light into an electrical signal representation of the radiation image.

[0004] Screens which are suitable for this application comprise e.g. a BaFX: Eu²⁺ phosphor or a divalent europium activated cesium halide phosphor wherein the halide is at least one of chloride and bromide or the like. The phosphor is deposited on top of a support layer such as a plastic film.

[0005] Some phosphors among which the above mentioned cesium halide phosphor are stable at normal temperature and humidity conditions but tend to be hygroscopic at high temperature and high humidity.

[0006] If a hygroscopic phosphor is exposed to moisture at elevated temperatures, the phosphor degrades. As a consequence sensitivity decreases. Since it is desirable that a radiographic system remains stable and has a long lifetime in all environmental conditions thus also in a hot and humid environment the above effects are unacceptable.

[0007] The most obvious way to avoid problems resulting from humidity is to coat the phosphor layer with a protective layer. However, it is common knowledge that such a protective layer leads to light piping. As a consequence of this effect the resolution of the screen degrades. This negative effect occurs even in case the protective layer is as thin as 10 micrometer.

OBJECTS OF THE INVENTION

[0008] It is an object of the present invention to provide a radiation detector wherein a radiation image is temporarily stored in a photostimulable phosphor screen that is stable and has a long life time under severe conditions regarding humidity and temperature.

[0009] Further objects of the present invention will become apparent from the description hereafter.

SUMMARY OF THE INVENTION

[0010] The above mentioned objects are realised by a radiation detector having the specific features defined in claim 1.

[0011] The inventors have found that high temperature on its own does not damage the system nor shorten its life cycle. Only the combination of high temperature together with high humidity degrades the screen.

[0012] The degradation is eliminated according to the present invention by providing a radiation detector comprising in addition to a phosphor screen the means for reading the radiation image from the screen and for occasionally erasing the screen. This detector is additionally provided with means for preventing humidity to enter the detector.

[0013] The phosphor screen is not taken out of the detector. It remains inside the enclosure of the detector during the exposure of the system to image-wise modulated radiation originating from irradiation of an object or a patient as well as during read out of the radiation image from an exposed screen and during occasional erasure of the screen between successive exposures.

[0014] According to one embodiment of the invention the detector is flushed by means of an inert gas such as N₂ gas, Ar gas, dried air or the like.

[0015] The gas may be circulated inside the system so that only a small quantity of the gas is needed.

[0016] Alternatively it can be pumped into the detector at one location and released at another location.

[0017] Specific features for preferred embodiments of the invention are set out in the dependent claims.

[0018] Further advantages and embodiments of the present invention will become apparent from the following description and drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

[0019]

Fig. 1 shows a radiation detector according to the present invention.

DETAILED DESCRIPTION OF THE INVENTION

[0020] An embodiment of a detector according to the present invention is shown in figure 1.

[0021] The detector comprises an enclosure (22).

[0022] Within the enclosure a photostimulable phosphor screen (23) is positioned. This screen for example comprises a divalent cesium halide phosphor, wherein said halide is at least one of chloride and bromide.

[0023] The enclosure further comprises a source of stimulating light (24) arranged for stimulating said phosphor screen and an array of transducer elements (25)

for capturing light emitted by the phosphor upon stimulation and for converting said light into an electrical signal representation.

[0024] In the illustrated embodiment the source of stimulating light is implemented as a linear light source (more specifically an array of laser diodes) and the array of transducer elements is also a linear array (more specifically an array of charge coupled device elements). This embodiment can be made very compact and provides fast read out.

[0025] The enclosure further comprises a linear erasing light source (26) arranged substantially parallel to the stimulating light source.

[0026] The enclosure still further comprises means (not shown) for transporting the assembly (27) of stimulating light source, erasing light source and array of transducer elements relative to the phosphor screen in a so-called sub-scan direction, indicated by arrow (28).

[0027] Means (29) are further provided for communicating the electrical signal representation output by the array of transducer elements to an external signal processing device.

[0028] In this re-usable radiation detector the phosphor screen remains inside the enclosure during irradiation, read out and erasure.

[0029] To guarantee a low humidity the detector is flushed with N_2 . The gas is pumped out of a common recipient such as a gas cylinder into a first opening (30) in the enclosure (22). The gas is released into the air through a second opening (not shown) in enclosure (22).

[0030] In this embodiment the stimulating light source and the array of transducer elements are arranged on opposite sides of the phosphor screen. In alternative embodiment these items may be arranged on the same side of the phosphor screen.

[0031] The stimuable phosphor screen in the several embodiments of the present invention comprises a divalent europium activated cesium halide phosphor. Such a phosphor is known in the art and has for example been disclosed in EP-A-174 875 (and US 5,028,509). The phosphor is especially well suited for manufacturing 'binderless' phosphor screens. Binderless phosphor screens provide optimal sharpness.

[0032] It is advantageous however to use a $CsX:Eu$ phosphor wherein X represents a halide selected from the group consisting of Br and Cl, which is obtained by the following method:

- mixing CsX with between 10^{-3} and 5 mol % of a Europium compound selected from the group consisting of EuX'_2 , EuX'_3 and $EuOX'$, X' being a member selected from the group consisting of F, Cl, Br and I,
- firing the mixture at a temperature above 450 °C
- cooling said mixture and
- recovering the $CsX:Eu$ phosphor.

[0033] A phosphor that has been obtained as a result of the above method of preparation has an increased conversion efficiency compared to the state of the art divalent europium activated cesium halide phosphor. The phosphor can be stimulated by means of a lower amount of stimulation energy.

[0034] A photostimulable phosphor screen using such a phosphor is preferably obtained by the method of

- 10 - preparing said $CsX:Eu$ phosphor by firing a mixture of said CsX with between 10^{-3} and 5 mol % of an Europium compound selected from the group consisting of EuX'_2 , EuX'_3 and $EuOX'$, X' being a halide selected from the group consisting of F, Cl, Br and I and
- 15 - applying said phosphor on a substrate by a method selected from the group consisting of physical vapor deposition, thermal vapor deposition,, chemical vapor deposition, radio frequency deposition and pulsed laser deposition.

[0035] This method of preparation is advantageous because it allows to deposit the phosphor in the form of needle-shaped crystals. These needle-shaped phosphor crystals act as light guides so that they reduce the lateral spreading of light in the phosphor layer. Reduced lateral light spread leads to images of higher resolution.

[0036] Alternatively a phosphor screen containing a $CsX:Eu$ stimuable phosphor, wherein X represents a halide selected from the group consisting of Br and Cl can also be manufactured by performing the steps of:

- bringing multiple containers of said CsX and an Europium compound selected from the group consisting of EuX'_2 , EuX'_3 and $EuOX'$, X' being a halide selected from the group consisting of F, Cl, Br and I in condition for vapor deposition and
- depositing, by a method selected from the group consisting of physical vapor deposition, thermal vapor deposition,, chemical vapor deposition, electron beam deposition, radio frequency deposition and pulsed laser deposition, both said CsX and said Europium compound on a substrate in such a ratio that on said substrate a CsX phosphor, doped with between 10^{-3} and 5 mol % of an Europium compound, is formed.

[0037] This method of preparation is advantageous because it likewise allows to deposit the phosphor in the form of needle-shaped crystals. These needle-shaped phosphor crystals act as light guides so that they reduce the lateral spreading of light in the phosphor layer. Reduced lateral light spread leads to images of higher resolution.

[0038] The above described phosphor and photostimulable phosphor screen have been described extensively in the following US provisional applications that are incorporated herein by reference: 60/159,004

and 60/142,276.

Claims

1. A radiation image detector comprising 5
 - a photostimulable phosphor screen,
 - at least one source of stimulating light arranged for stimulating said phosphor screen,
 - an array of transducer elements arranged for capturing light emitted by the phosphor screen upon stimulation and for converting said light into an electrical signal representation of said image, 10
 - an enclosure enclosing said photostimulable phosphor screen, said assembly of stimulating light source and said array of transducer elements, 15
 - interfacing means for communicating said electrical signal representation to an external signal processing device, 20
 - means for preventing humidity from entering said enclosure.

2. A radiation image detector according to claim 1 wherein said means for preventing humidity from entering said enclosure comprise means for flushing said enclosure with an inert gas. 25

3. A radiation image detector according to claim 1 wherein said inert gas is N_2 . 30

4. A radiation image detector according to claim 2 wherein said enclosure comprises a gas inlet arranged for coupling to a gas container and a gas outlet. 35

5. A radiation image detector according to claim 2 wherein said means for flushing said enclosure with inert gas comprise means for circulating said gas inside said enclosure. 40

6. A detector according to claim 1 wherein said linear stimulating light source is a linear array of laser diodes. 45

7. A detector according to claim 1 wherein said linear array of transducer elements is a linear array of charge coupled device elements. 50

8. A detector according to claim 1 wherein said phosphor screen comprises a divalent europium activated cesium halide phosphor wherein said halide is at least one of chloride and bromide. 55

9. A detector according to claim 1 wherein said photostimulable phosphor screen is obtainable by the following steps:
 - mixing CsX with between 10^{-3} and 5 mol % of a Europium compound selected from the group consisting of EuX'_2 , EuX'_3 and $EuOX'$, X' being a member selected from the group consisting of F, Cl, Br and I,
 - firing the mixture at a temperature above 450 °C
 - cooling said mixture and
 - recovering the CsX:Eu phosphor.

10. A detector according to claim 1 wherein said phosphor screen is obtained by the steps of
 - preparing said CsX:Eu phosphor by firing a mixture of said CsX with between 10^{-3} and 5 mol % of an Europium compound selected from the group consisting of EuX'_2 , EuX'_3 and $EuOX'$, X' being a halide selected from the group consisting of F, Cl, Br and I and
 - applying said phosphor on a substrate by a method selected from the group consisting of physical vapour deposition, thermal vapour deposition, chemical vapour deposition, radio frequency deposition and pulsed laser deposition.

11. A detector according to claim 1 wherein said phosphor screen is obtainable by the steps of
 - bringing multiple containers of said CsX and an Europium compound selected from the group consisting of EuX'_2 , EuX'_3 and $EuOX'$, X' being a halide selected from the group consisting of F, Cl, Br and I in condition for vapour deposition and
 - depositing, by a method selected from the group consisting of physical vapour deposition, thermal vapour deposition, chemical vapour deposition, electron beam deposition, radio frequency deposition and pulsed laser deposition, both said CsX and said Europium compound on a substrate in such a ratio that on said substrate a CsX phosphor, doped with between 10^{-3} and 5 mol % of an Europium compound, is formed.
